OF WOLLONGONG
AUSTRALIA

Z as a specification language

- Based on typed set theory
- Includes schemas, an effective low-level structuring facility
- Schemas are specification building blocks
- Graphical presentation of schemas make Z specifications easier to understand
- Z is one of the most widely used model-based specification languages

An example in Z

```
int iroot(int a)
/* Integer square root */
{
    int i, term, sum;

    term=1; sum=1;
    for (i=0; sum <= a; i++)
        term=term+2;
        sum=sum+term;
    }
    return i;
}
```

Computer the integer square root

- N stands for natural number, 0, 1, 2,..., so both the input and output must be a natural number
- It explains what happens when the argument does not have the perfect integer square root, i.e., return the largest integer square root

$$iroot : \mathbb{N} \rightarrow \mathbb{N}$$
$$\forall a : \mathbb{N} \bullet$$
$$iroot(a) * iroot(a) \leq a < (iroot(a) + 1) * (iroot(a) + 1)$$

Z schemas

- Introduce specification entities and defines invariant predicates over these entities
- A schema includes
 - A name identifying the schema
 - A signature introducing entities and their types
 - A predicate part defining invariants over these entities
- Schemas can be included in other schemas and may act as type definitions
- Names are local to schemas

Introducing schemas: Text Editor Example

Model a simple text editor

- The text editor can only deal with texts composed of characters
- The text editor has the size limit, i.e., **65535** characters
- A document can be modelled as two texts and the cursor, i.e., **left** indicates the text before the cursor, and **right** indicate the text following the cursor
- Users can insert new character in the document to the left of the cursor
- Users can move the cursor forward or backward without changing the existing characters in the document
- The cursor locates the end of file (EOF) when there is no character after the cursor

Basic types and abbreviation definition

- We declare a *basic type*: the set of all characters first.
- Then we define an *abbreviation definition* for a text: a sequence of characters.

[CHAR]

TEXT == seq CHAR

- CHAR is the character set, no need to specify the details, might be ASCII
- CHAR is a full-fledged Z data type.
- In Z, a new data type can be introduced by writing its name inside brackets
- In Z, *seq* is used to defined a sequence of any type.
- *==* indicates *TEXT* is an abbreviation for *seq CHAR*

Axiomatic descriptions

In Z, we use axiomatic descriptions to define constants

$$\begin{array}{|l} \textit{maxsize} : \mathbb{N} \\ \hline \textit{maxsize} \leq 65535 \end{array}$$

- *maxsize* is a non-negative integer
- *maxsize* can be any number up to 65,535
- Constants declared in axiomatic descriptions are global

State schema

In Z, state schemas indicate the states of the system, i.e., collections of state variables and their values. State variables are also called components.

left and *right* are the two state variables for our editor.

- The variables declared inside the schema box are *local*.
- *left*, *right* are TEXT
- The document can hold no more than *maxsize* characters.
- $left \frown right$ construct the whole text from *left* and *right*
- *#* is the size operator

Initialization schema

Every system must have a start up state. In Z, this state is described by a schema conventionally named *Init*.

- *Init* schema includes *Editor* schema
- All the declarations and predicates in *Editor* schema apply to *Init* schema as well, so *Init* schema can use the local state variables *left* and *right* from *Editor* schema
- $\langle \rangle$ is the empty sequence

Operation schema

In Z, we define operation schemas to indicate how the system's states are changed. For example, the user can insert characters into our editor.

The *Insert* schema below defines how a single character is inserted in the document to the left of the cursor.

| *printing* : $\mathbb{P}CHAR$

Insert

$\Delta Editor$

$ch? : CHAR$

$ch? \in printing$

$left' = left \frown \langle ch? \rangle$

$right' = right$

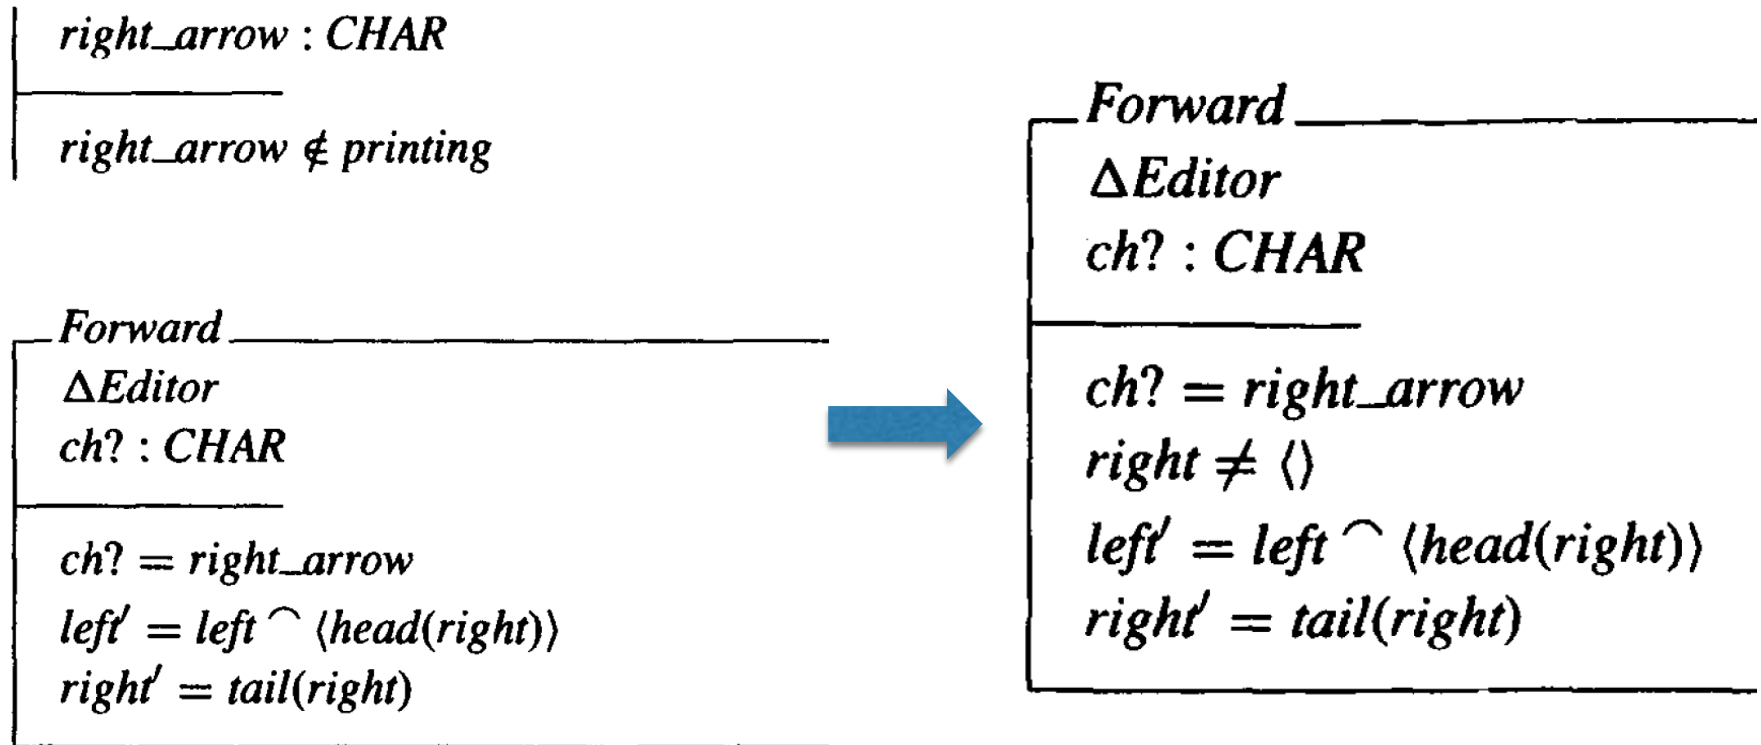

Operation schema

- A schema name prefixed by the Greek letter Delta (Δ) means that the operation changes some or all of the state variables.
- ? Indicates the input of the operation schema
- Unprimed variables *left* and *right* denote the texts before the insert
- Primed variables *left'* and *right'* denote the texts after the insert.
- $ch? \in \text{printing}$ is the pre-condition, and it must be true before the insert operation can occur.
- The rest of the predicate is a post-condition: it describes the state of the editor after the operation.
- $left' = left \frown \langle ch? \rangle$ tells the new character is appended to the end of text preceding the cursor
- $right' = right$ says the text following the cursor does not change. In Z, we also must specify unchanged things.

Forward operation

This schema defines the operation by pressing the right arrow key on the keyboard.

- *head()* returns the first element of a sequence
- *tail()* returns remaining sequence without the first element

Operation specification

- Operations may be specified incrementally as separate schema then the schemas combined to produce the complete specification
- Define the 'normal' operation as a schema
- Define schemas for exceptional situations
- Combine all schemas using the disjunction (or) operator

Schema calculus

The editor can't crash, and it must be robust. We should define a total version of forward operation. We can define it in pieces, where each piece is a schema. Then we will use the schema calculus to put them together. This is a common way in Z to define complex operations.

<i>EOF</i>
<i>Editor</i>
<i>right</i> = $\langle \rangle$

<i>RightArrow</i>
<i>ch?</i> : <i>CHAR</i>
<i>ch?</i> = <i>right_arrow</i>

$$T_Forward \hat{=} Forward \vee (EOF \wedge RightArrow \wedge \Xi Editor)$$

- A schema name prefixed by the Greek letter Xi (Ξ) means that the state of the schema will not be changed

Another Example: A Water Tank

- A water tank contains a container and indicator;
- The container contains water, and the indicator reads and indicates the water level;
- The container has limits in both maximal and minimal water level;
- If the water level drops below the danger level, the indicator's light will turn on;
- When the indicator's light turning on, we shall add water to the container. However, the total water in the container shall no more than the capacity of the container;
- When the water level is above the danger level, the indicator's light turns off;

Container schema: State Schema

Indicator schema: State Schema

Indicator

light:{off, on}

reading: **N**

danger_level: **N**

light = on \Leftrightarrow reading \leq danger_level

Storage tank schema: Init Schema

Storage_tank

Container
Indicator

reading = contents
capacity = 5000
danger_level = 50

Full specification of storage tank schema

Storage_tank

contents: **N**

capacity: **N**

reading: **N**

danger_level: **N**

light: {off, on}

$\text{contents} \leq \text{capacity}$

$\text{light} = \text{on} \Leftrightarrow \text{reading} \leq \text{danger_level}$

$\text{reading} = \text{contents}$

$\text{capacity} = 5000$

$\text{danger_level} = 50$

A partial spec. of a fill operation

Fill-OK

Δ Storage_tank
amount?: **N**

the amount of water
being added

$\text{contents} + \text{amount?} \leq \text{capacity}$
 $\text{contents}' = \text{contents} + \text{amount?}$

Storage tank fill operation

OverFill

\exists Storage-tank
amount?: \mathbb{N}
r!: seq CHAR

capacity < contents + amount?
r! = “Insufficient tank capacity – Fill cancelled”

“!” Indicates the output,
which is a sequence

Fill

Fill-OK \vee OverFill

Data dictionary modelling

- A data dictionary may be thought of as a mapping from a name (the key) to a value (the description in the dictionary)
- Operations are
 - Add: makes a new entry in the dictionary or replaces an existing entry
 - Lookup: given a name, returns the description.
 - Delete: deletes an entry from the dictionary
 - Replace: replaces the information associated with an entry

Data dictionary entry: state schema

DataDictionaryEntry

entry: NAME

desc: seq CHAR

type: Sem_model_types

creation_date: DATE

#desc ≤ 2000

Data dictionary: state schema

DataDictionary

DataDictionaryEntry

ddict: NAME → {DataDictionaryEntry}

Specification using functions

- A function is a mapping from an input value to an output value
 - $\text{SmallSquare} = \{1 \rightarrow 1, 2 \rightarrow 4, 3 \rightarrow 9, 4 \rightarrow 16, 5 \rightarrow 25, 6 \rightarrow 36, 7 \rightarrow 49\}$
- The domain of a function is the set of inputs over which the function has a defined result
 - $\text{dom SmallSquare} = \{1, 2, 3, 4, 5, 6, 7\}$
- The range of a function is the set of results which the function can produce
 - $\text{ran SmallSquare} = \{1, 4, 9, 16, 25, 36, 49\}$

The function SmallSquare

Domain (SmallSquare)

Range (SmallSquare)

Data dictionary - initial state

Init-DataDictionary

DataDictionary

ddict = \emptyset

Add and Lookup operations

Add_OK

Δ DataDictionary
name?: NAME
entry?: DataDictionaryEntry

name? \notin dom ddict
ddict' = ddict \cup {name? \mapsto entry?}

Lookup_OK

Ξ DataDictionary
name?: NAME
entry!: DataDictionaryEntry

name? \in dom ddict
entry! = ddict (name?)

Add and Lookup operations

Add_Error

\exists DataDictionary

name?: NAME

error!: seq CHAR

name? \in dom ddict

error! = "Name already in dictionary"

Lookup_Error

\exists DataDictionary

name?: NAME

error!: seq CHAR

name? \notin dom ddict

error! = "Name not in dictionary"

Function over-riding operator

- Replace Entry uses the function overriding operator (written \oplus).

This adds a new entry or replaces an existing entry.

- phone = { Ian \rightarrow 3390, Ray \rightarrow 3392, Steve \rightarrow 3427 }
- The domain of phone is {Ian, Ray, Steve} and the range is {3390, 3392, 3427}.
- newphone = {Steve \rightarrow 3386, Ron \rightarrow 3427 }
- phone \oplus newphone = { Ian \rightarrow 3390, Ray \rightarrow 3392, Steve \rightarrow 3386, Ron \rightarrow 3427 }

Update operation

update

Δ DataDictionary

name?: NAME

entry?: DataDictionaryEntry

$\text{ddict}' = \text{ddict} \oplus \{\text{name?} \mapsto \text{entry?}\}$

Deleting an entry

- Use the domain anti-restriction operator (written \Leftarrow), which given a name, removes that name from the domain of the function
 - $\text{phone} = \{ \text{Ian} \rightarrow 3390, \text{Ray} \rightarrow 3392, \text{Steve} \rightarrow 3427 \}$
 - $\{\text{Ian}\} \Leftarrow \text{phone}$
 - $\text{Phone} = \{ \text{Ray} \rightarrow 3392, \text{Steve} \rightarrow 3427 \}$

Delete entry

Delete_OK

Δ DataDictionary

name?: NAME

name? \in dom ddict

ddict' = {name?} \Leftarrow ddict

From informal to formal description

- Informal specification
 - Text-based
 - Diagrams (data flow diagram, state diagram)
 - etc.
- A control program for the therapist's console on a radiation therapy machine

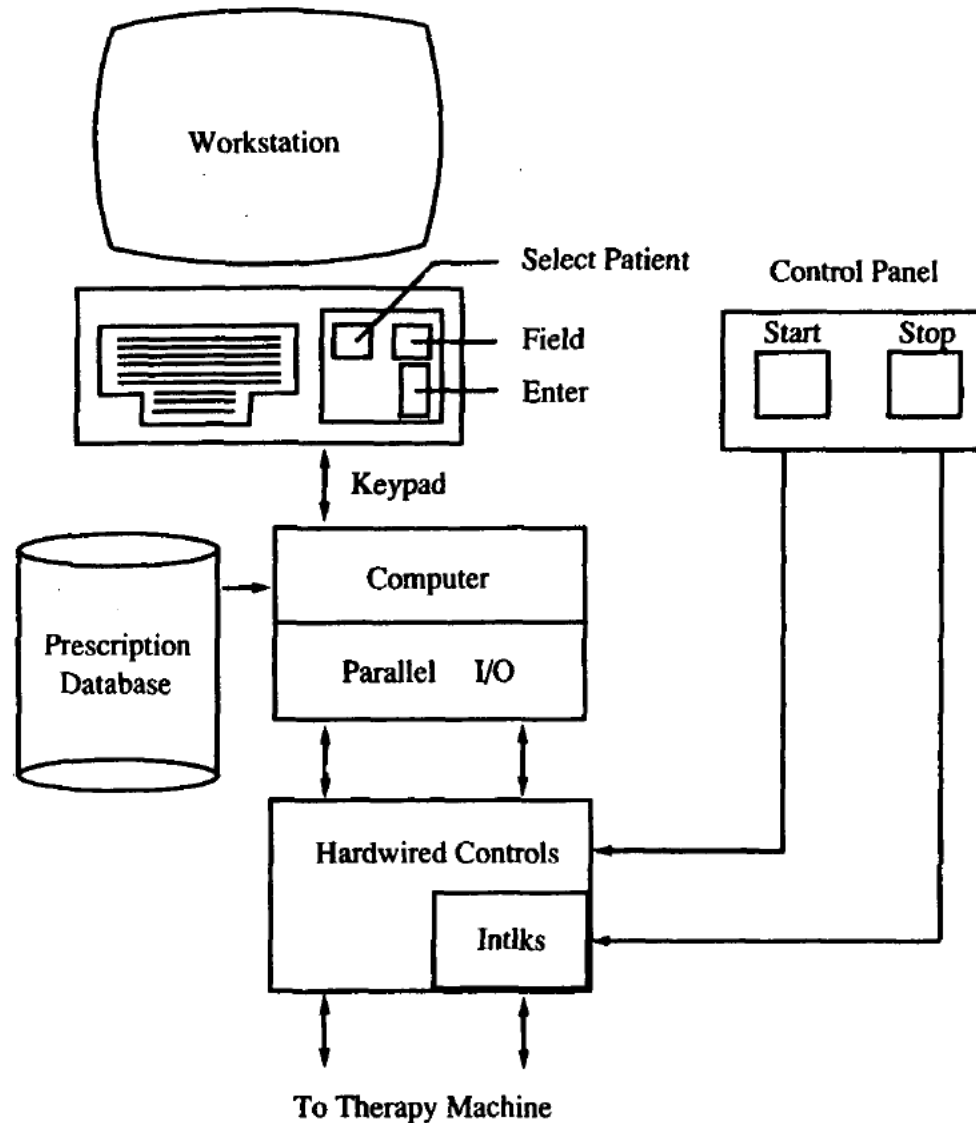

A control program for a therapy machine

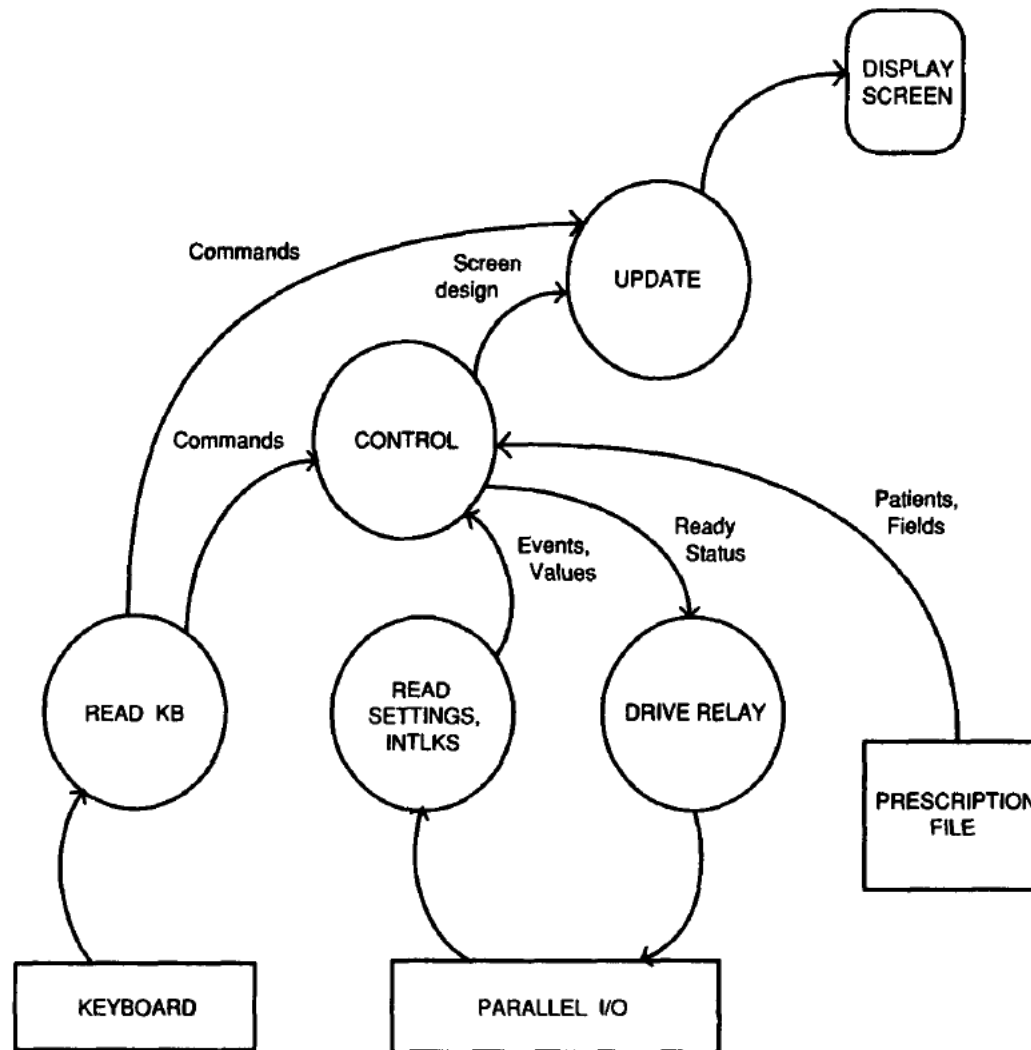

Informal requirements

- The system has a database of prescriptions for many patients
- Each prescription contains fields to define machine settings.
- The therapist operates the control program by pressing labelled function keys
- The control program is only responsible for checking the prescribed settings and actual settings agree
- Select Patient Key is used to choose a patient's prescription from the system. Enter Key is used to confirm the selection
- When all the settings match the prescription, the control program closes its relay and the workstation indicates the machine is ready
- Start button is used to turns the beam on
- Stop button is used to turns the beam off

Therapy control console block diagram

Informal model: Data flow diagram

Informal model: state diagram

Informal model: state transition table

	SELECT PATIENT	SELECT FIELD	ENTER	ok	START	STOP	intlk
