

$T_1$	$T_2$	$T_3$
	read total order	total_number
insert		total_number + 1
	read total order	total_number + 1

I think we should choose repeatable read.

Because in this case, using insertion order, serializable isolation should be better than read commit, because there are some non-repeatable read situations, and the read commit level cannot handle this situation.

Repeatable reads are usually used to avoid non-repeatable reads, and the serializable level contains the functions that repeatable reads can perform.
